Jesse Gelsinger, was not sick before died at all the 18-years-old worker, was the only first person publicly described as having died at the clinical experiment of the gene transfer research at 1999. He only suffered from ornithine transcarbamylase deficiency, the X-linked hereditary disease of the human, the signs of which comprise the incapability to metabolize liquid-the consequence of protein analysis. He was injected with the adenoviral vector holding the approved sequence to determine the protection of the operation as well as died four days later, despite not being ill earlier than the research. The important topic in the investigation was a conflict of interest (COI). The disease was controlled with a low-protein diet and medications, 32 pills every day.
